## 1. INTRODUCTION

## PEDESTRIAN CROSSING STUDY NORTH INDIAN CREEK DRIVE AT ROWLAND STREET

This pedestrian crossing study was conducted to evaluate the pedestrian activity crossing North Indian Creek Drive at Rowland Street. This study analyzes the various options that can be utilized to provide a safer method of crossing North Indian Creek Drive. The study area is shown in Figure 1.

Figure 1 - Study Intersection Map

## Methodology

Initial evaluations were made of the various types of pedestrian crossings utilized in Georgia. The Georgia Department of Transportation (GDOT) and the Manual on Uniform Traffic Control Devices (MUTCD) specify criteria for deciding where, if, and the type of marked crosswalk that should be installed. The applicable criteria required to warrant approved types of pedestrian crossings was gathered and was used in identifying the necessary data. The collected data included 12-hour (6:30 AM to 6:30 PM), Pedestrian count data, vehicular count data, and 24 -hour vehicular speed data. All data was collected on a typical weekday with good weather to provide accurate count data for the analysis. The various types of pedestrian crossings were analyzed for potential operation at this location. The concept proposed by the PATH foundation was analyzed with comments provided for potential modifications.

## 2. EXISTING CONDITIONS

## PEDESTRIAN CROSSING STUDY NORTH INDIAN CREEK DRIVE AT ROWLAND STREET

## Study Intersection Characteristics

The study intersection at North Indian Creek Drive and Rowland Street is located in Clarkston, GA. This intersection encompasses a major collector road and a local road. North Indian Trail Drive is a two-lane two-way roadway in the vicinity of the study area. The speed limit on North Indian Trail Drive is posted at 35 mph . Rowland Street is a two-lane two-way street with a speed limit of 25 mph in the vicinity of study area. The existing lane geometry and traffic control for the study intersection area are shown below in Figure 2.

Figure 2 - Study Intersection Existing Travel Lanes and Traffic Control

Rowland Street forms a four-legged intersection with North Indian Creek Drive. The Northbound approach serves as one of the two access points to a series of residential driveways, and the

Southbound approach serves as one of two access points to a series of residential properties located to Northeast of the study intersection. Both the Northbound and Southbound approaches of Rowland Street are stop sign controlled and North Indian Creek Drive is free flow.

## Existing Traffic Flow Data

12-hour Vehicle tube counts, pedestrian counts and 24-hour vehicle speed data and were collected on Tuesday, February $7^{\text {th }}, 2017$ at the study intersection. Table 1 shows the pedestrian activity at North Indian Creek Drive and Rowland Street Intersection. During AM and PM peak periods pedestrian numbers corresponding to the directional column in the table are the pedestrians crossing the corresponding leg of the intersection.

Table 1 - Pedestrian Data Collection Results

| North Indian Creek Drive \& Rowland Street |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| AM Peak Observed 2/7/2017 8:45 AM - 9:45 AM |  |  |  |  |  |
| Time Period | East | West | North | South | Total |
| 8:45 AM - 9:00 AM | 4 | 0 | 2 | 2 | 8 |
| 9:00 AM - 9:15 AM | 1 | 1 | 0 | 2 | 4 |
| 9:15 AM - 9:30 AM | 0 | 0 | 0 | 5 | 5 |
| 9:30 AM - 9:45 AM | 0 | 0 | 2 | 0 | 2 |
| Total | 5 | 1 | 4 | 9 | 19 |
| PM Peak Observed 2/7/2017 1:30 PM - 2:30 PM |  |  |  |  |  |
| Time Period | East | West | North | South | Total |
| 1:30 PM - 1:45 PM | 2 | 0 | 3 | 1 | 6 |
| 1:45 PM - 2:00 PM | 1 | 1 | 2 | 3 | 7 |
| 2:00 PM - 2:15 PM | 1 | 2 | 0 | 2 | 5 |
| 2:15 PM - 2:30 PM | 4 | 1 | 0 | 2 | 7 |
| Total | 8 | 4 | 5 | 8 | 25 |

The pedestrians that did cross were observed to cross North Indian Creek Drive frequently during AM and PM peak hours. During the AM peak hour, 6 out of the total 19 pedestrians crossed North Indian Creek Drive. During the PM peak hour, 12 out of the total 25 pedestrians were observed to cross North Indian Creek Drive. The existing conditions show crosswalks located on north and south side of the intersection to cross Rowland Street. Crosswalks were not present on the east and west side of the intersection to cross North Indian Creek Drive.

Figure 3-Crosswalks on North and South Side of the Intersection

## 3. POTENTIAL SOLUTIONS / ANALYSIS

## PEDESTRIAN CROSSING STUDY NORTH INDIAN CREEK DRIVE AT ROWLAND STREET

There are various types of pedestrian crossings that can be utilized to allow for a safer pedestrian crossing than what currently exists in the study area today. The following is a list of the various types of crossings and descriptions of their operation. While GDOT's approval of a pedestrian crossing treatment installation, if applicable, is not required since North Indian Creek Drive is not a designated state route, this report still uses GDOT's criteria for installing a pedestrian crossing treatment. These various types of pedestrian crossings vary in amount of warning for the vehicle, the indications for the vehicle and pedestrian, and the method of activation.

## Treatment \#1: Pedestrian Sign with No Flashing Beacons

The pedestrian sign with no flashing beacons is comprised of a crosswalk with a static pedestrian sign (W11-2). This type of crossing advises the driver of potential pedestrian activity in the vicinity: It provides identification of a crosswalk, but does not give drivers a different message when there is a pedestrian present at the crosswalk. This type of crossing is utilized in lower pedestrian volume areas and sections of roadway that have no sight distance restrictions, thereby providing drivers with a clear line of sight to the crosswalk. It should be noted that there are no required pedestrian volumes or vehicular speeds and volumes to warrant this type of crossing treatment. However, this type of treatment is typically used in low pedestrian volume locations. The highest maximum pedestrian crossing volume at any hour of the day of pedestrian data collection is 12 . Therefore, this type of pedestrian treatment can be utilized. Figure 4 shows the intersection of Peeler Road and Lakeside Drive in Dunwoody, which is an example of a pedestrian crossing with no flashing beacons.

Figure 4 - Example of Pedestrian Crossing with No Flashers

## Treatment \#2: Pedestrian Sign with Wig Wag Flashers

The pedestrian sign with wig wag flasher type crossing is comprised of a crosswalk with a pedestrian sign (W11-2) that includes wig wag flashers on both vehicular approaches. The wig wag flashers operate continuously (24-hours a day) and thus are not activated by the presence of a pedestrian. No pedestrian button is present at this type of crossing. This type of crossing warns the driver of a potential pedestrian crossing but does not operate any differently with a pedestrian present or absent. This type of crossing is installed in lower pedestrian volume areas and provides a warning to the driver that pedestrian activity is common in the area. However, there are no specific pedestrian volumes or vehicular volumes and speed criteria to warrant this type of crossing treatment. Since the maximum number of pedestrians crossing the North Indian Creek Drive at any hour of the day of pedestrian data collection is 12, this type of pedestrian treatment can be utilized. Figure 5 shows an example of a midblock pedestrian crossing in downtown Decatur, which has continuous wig wag flashers.

Figure 5 - Example of Pedestrian Crossing with Continuous Wig Wag Flashers

## Treatment \#3: Pedestrian Sign with Wig Wag Flashers Activated by Pedestrian

The pedestrian sign with wig wag flasher type crossing is comprised of a crosswalk with a pedestrian sign (W11-2) that includes wig wag flashers on both vehicular approaches. The wig wag flashers operate for a short duration of time only when there is the presence of a pedestrian. The flashers are activated by a pedestrian push button, which is present at this type of crossing. This type of crossing warns the driver of a pedestrian crossing at this location. This type of crossing is utilized in lower pedestrian volume areas and provides a warning to the driver that pedestrian activity is common in the area. The pushbutton activation feature warns a driver that a pedestrian is either waiting to cross, in the process of crossing, or has just finished crossing. This type of installation is no longer utilized, and has been replaced with Treatment \#4. Figure 6 shows the midblock pedestrian crossing on Peachtree Corners Circle located just northeast of the intersection of with Eastman Trail in Peachtree Corners. Treatment \#4, which consists of a Pedestrian sign with Rapid Flashing Beacon (RFB), is described next.

Figure 6 - Example of Pedestrian Crossing with Wig Wag Flashers Active by Push Button

## Treatment \#4: Pedestrian Sign with Rapid Flashing Beacon (RFB)

The pedestrian sign with RFB is comprised of a crosswalk with a pedestrian sign (W11-2) that includes an RFB. The beacon is activated by a pedestrian button located at each end of the crosswalk. The RFB remains dark until activated by the button. A center refuge island can be in the center of the roadway to shorten the crossing distance and provide a safer crossing. No indications are present for the pedestrian. This type of crossing can be used in lower to moderate pedestrian volume areas and provides a warning to the driver when a pedestrian is present. However, there are no specific pedestrian volumes or vehicular volume and speed criteria to warrant this type of crossing treatment. Figure 7 shows the midblock crossing with an RFB on Tilly Mill Road at the city limit of the city of Dunwoody. With 12 pedestrians during peak hour, an RFB could be one of the potential pedestrian crossings used at this intersection.

Figure 7 - Example of Pedestrian Crossing with Pedestrian Activated Rapid Flashing Beacon

## Treatment \#5: Hawk Signal

A Hawk signal is a High intensity $\underline{\text { Activated cross Walk. Depending upon the width of the roadway }}$ and the median size, the crossing can be a one or two stage crossing. A pedestrian utilizing the crossing presses the button to activate the first signal, when the traffic signal turns red, a "walk" indication allows the pedestrian to cross the first stage. Once reaching the center Refuge Island the pedestrian presses the second button to activate the second signal. The vehicular indication is a three section signal head with two side by side red indications above a yellow indication. The vehicular signals are dark until activated by the pedestrian, while the pedestrian signals are a solid orange hand (don't walk) indication. Once activated by the pedestrian, the vehicular signal flashes yellow to warn drivers that the signal has been activated. The vehicular signal then turns to solid yellow to prepare the drivers to stop. Both red vehicular indications turn solid red while the pedestrian signal changes to a white walking man. After the walk time has elapsed the pedestrian clearance times out, the pedestrian signal changes to a flashing orange hand and a countdown timer, while the vehicular indication changes to a flashing red. The flashing red allows a vehicle to proceed through the crosswalk after the pedestrian has crossed its path. After the countdown time has elapsed, the signals revert back to solid orange hand for the pedestrian and dark for the vehicle. Figure 8 shows the midblock signalized crossing along SR 155/Candler Road in Decatur, which is an example of a pedestrian crossing with a hawk signal.

Figure 8 - Example of Pedestrian Crossing with Hawk Signal

Guidelines for the installation of pedestrian signals on Low-speed roadways (speeds of 35 MPH or less) were applied from the MUTCD for the observed crossing locations within the study area, and are shown below. The posted speed limit along this section of North Indian Creek Drive is 35 MPH and the overall $85^{\text {th }}$ Percentile speed was measured to be 32 MPH. Therefore, Figure 9 is utilized for determining if a Hawk signal is warranted at this location. Each curve has an associated expected crosswalk length (L), if a marked crosswalk were to be installed. North Indian Creek Drive is a two-lane two-way roadway. The measured curb to curb crossing distance at the study intersection is approximately 50 feet. The highest one hour peak pedestrian crossings occur between 1:30 PM and 2:30 PM, and totaled 12 crossings. The bi-directional traffic volume between 1:30 PM and 2:30 PM is 1071 vehicles per hour.

As can be seen, the combination of the major street total bi-directional traffic and the number of pedestrians crossing in the peak hour falls below the applicable curve. Also, the number of pedestrian crossings during the peak hour does not currently meet the threshold of 20 pedestrian crossings per hour; therefore, warrant for installing a Hawk Signal was NOT met for installation.

Figure 9-Guidelines for Installing HAWK Signal (Low-Speed Highways)

## Treatment \#6: Traffic Signal

A traffic signal provides the highest level of pedestrian crossing protection across all approaches to an intersection that are signalized. Both vehicles and pedestrians each have their own signal indication. A pedestrian utilizing a crossing at a signalized intersection presses the push button to place a call into the signal controller. Depending upon the programming of the signal at the intersection, the pedestrian is given a "walk" indication either at the same time as the adjacent vehicular movement (e.g. concurrent pedestrian phase) or by itself (e.g. exclusive pedestrian phase). After the "walk" indication is given, a flashing hand with or without a countdown of time remaining to cross before right of way is given to another direction and vehicular movement.

Warrant four (4) in the traffic signal warrants section of the MUTCD is shown below. For 1 hour (any four consecutive 15 -minute periods) of an average day, the plotted point representing the vehicles per hour on the major street (total of both approaches) and the corresponding pedestrians per hour crossing the major street (total of all crossings) falls above the curve in Figure 10 . The highest one hour peak pedestrian crossings occurred between 1:30 PM and 2:30 PM, and totaled 25 crossings of which 12 were accounted crossing the North Indian Creek Drive. The bi-directional traffic volume between 1:30 PM and 2:30 PM is 1071 vehicles per hour.

As can be seen, the combination of the major street total bi-directional traffic and the number of pedestrians crossing the major street in the peak hour falls below the curve. Additionally, the number of pedestrian crossings during the peak hour falls below the minimum threshold of 133 pedestrian crossings per hour; therefore, Warrant 4 is NOT met for the installation of a standard traffic signal.

Figure 10 - Warrant 4 (Pedestrian Peak Hour), Traffic Signal Warrants Analysis

"Note: 133 pph applles as the lower threshold volume.

## 4. CONCEPT REVIEW

## PEDESTRIAN CROSSING STUDY NORTH INDIAN CREEK DRIVE AT ROWLAND STREET

An analysis of the concept proposed by PATH foundation was performed to study the effect of restricting left-turns at the intersection. Synchro models were created for AM and PM peak hour conditions for both existing and proposed scenarios. The existing scenario was modeled with the exact lane configuration that exists at this intersection today. The proposed scenario was modelled with the lane configuration proposed by the path foundation.

It was observed that the proposed concept did not negatively affect the traffic operations at the intersection. In fact, eliminating the left turns on North Indian Creek Drive and right-in right-out treatment on Rowland street slightly improved the traffic operations at the intersection. The Northbound and Southbound approaches experienced lesser delays due to the elimination of through and left turn movements. Since the traffic control for the Eastbound and Westbound approaches is free and left turns are prohibited, these movements were shown to have zero delays. Table 2 and Table 3 shows the comparison of HCM delays between existing and proposed models for AM and PM peak hours respectively.

Table 2 - Operational Analysis Results AM Peak Hour

| N Indian Creek Dr @ Rowland St AM Peak |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: |
|  | HCM Control Delay (S) |  |  |  |
|  | Eastbound | Westbound | Northbound | Southbound |
| Existing | 0.3 | 0.2 | 38.3 | 29.1 |
| Proposed | 0 | 0 | 11.4 | 12.9 |

Table 3 - Operational Analysis Results PM Peak Hour

| N Indian Creek Dr @ Rowland St PM Peak |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: |
|  | HCM Control Delay (S) |  |  |  |
|  | Eastbound | Westbound | Northbound | Southbound |
| Existing | 0.1 | 0.3 | 40.9 | 42 |
| Proposed | 0 | 0 | 15.7 | 12 |

The existing conditions do not provide any protected pedestrian crossing across North Indian Creek Road. The concept proposed by PATH foundation provides protected pedestrian crossings with crosswalks on both the east and west side of the intersection. Few revisions were made to the concept proposed by the PATH, which will be discussed in the conclusions chapter.

## 5. CONCLUSIONS \& RECOMMENDATIONS

## PEDESTRIAN CROSSING STUDY NORTH INDIAN CREEK DRIVE AT ROWLAND STREET

Based upon the analyses of peak hour data, both a traffic signal (Treatment \#6) and a Hawk Signal (Treatment \#5) are not currently warranted. An argument could be made that this improvement to the safety of this crossing will increase the number of crossing per hour and therefore could warrant one of these options. Since Treatment \#3 is no longer installed, the available remaining options are to install Treatments \#1, \#2, and \#4. Installing Treatment \#2 may not be effective given the continuous wig-wag flashers, thereby desensitizing drivers to the presence of a pedestrian. An RFB (Treatment \#4) could be an effective installation, due to the pedestrian actuated nature of the device; however, this treatment has the following guidance provided in the MUTCD:

Guidance: When an engineering study finds that installation of a pedestrian hybrid beacon is justified, then:
A. The pedestrian hybrid beacon should be installed at least 100 feet from side streets or driveways that are controlled by STOP or YIELD signs,
B. Parking and other sight obstructions should be prohibited for at least 100 feet in advance of and at least 20 feet beyond the marked crosswalk, or site accommodations should be made through curb extensions or other techniques to provide adequate sight distance,
C. The installation should include suitable standard signs and pavement markings, and
D. If installed within a signal system, the pedestrian hybrid beacon should be coordinated.

Utilizing an RFB treatment could require the pedestrian crossing to be relocated at least 100 feet to the east or west of the intersection. Since the pedestrians and bicyclists use Rowland street to travel north and south, moving the crosswalk away from the intersection would not be practical. Installation of an RFB is a decision at the discretion of the City per the MUTCD guidelines. Wolverton supports this option for this specific use provided the right-in-right-out improvements are installed on both approaches of Rowland Street. A standalone crosswalk without any beacons (Treatment \#1), with signs commanding vehicles to stop for pedestrians within the crosswalk is the other option for this location.

Few alterations were done to the concept proposed by the PATH foundation. A new concept was developed with one crosswalk to cross the North Indian Creek Drive. One crosswalk is expected to be efficient and provides the drivers with one pedestrian conflict point. Two crosswalks require drivers to watch for pedestrians crossing at two different locations. As per the revised proposed concept, the pedestrian crossing on North Indian Creek Drive are made in two stages. Pedestrians start crossing from the raised triangular islands on either the north or south side of the intersection. When there is an adequate gap they cross one travel lane of North Indian Creek Drive and reach the refugee island in the center. When an adequate gap is available they cross the second travel lane and reach the triangular island on the other side. The revised concept is shown in the Figure 11.
